

**System and Method for Providing Caller Information
Across Heterogeneous Networks**

ABSTRACT

A system and method for providing caller information
5 across heterogeneous networks is provided. A Name
Resolution Adapter (NRA) receives a message from a
destination central office which includes a caller's
telephone number and a call recipient's telephone number.
The NRA retrieves a call recipient contract and caller
10 authorization entries, and identifies caller fields that
the call recipient is authorized to receive. The NRA
includes the identified caller fields in a message to a
Service Control Point (SCP), whereby the SCP retrieves
caller attributes corresponding to the caller fields from a
15 Line Information Database (LIDB). The SCP forwards the
caller attributes to the NRA. In turn, the NRA includes
the caller attributes in a message and forwards the message
to the call recipient over a computer network. The call
recipient processes a corresponding telephone call using
20 the caller attributes that are included in the message.
